

HIGH-STRENGTH EROSION ELECTRODE

[0001] This application is a continuation-in-part of U.S. Serial No. 09/202 211, filed December 9, 1998.

FIELD OF THE INVENTION

[0002] The invention relates to a method for the manufacture of a wire electrode for the spark-erosion process and a wire electrode for this method, which consists of a core of steel, an intermediate layer of copper or a high copper-containing alloy, and an outer layer with at least 40% zinc or a core of steel and a zinc alloy outer layer having a zinc content of from 40-60%.

BACKGROUND OF THE INVENTION

[0003] Wire electrodes, which are designed with multiple layers, which have a core of steel, an intermediate layer of copper arranged around the core, and an outer zinc-containing layer, are known, for example, from the DE-PS 29 06 245. All known wire electrodes, which are constructed with a steel core, do indeed have an increased strength compared with copper or brass electrodes, however, all of these erosion electrodes have the disadvantage that if they have comparatively high strengths, their electrical conductivity is very low and merely reaches $8 \text{ S}\cdot\text{m}/\text{mm}^2$. This comparatively high tensile strength is particularly advantageous for the cutting of high or thick workpieces or, however, also for the cutting of very small parts since high wire tensions are here demanded. However, these known wire electrodes have the disadvantage that their erosion performance is relatively low. In particular, in the case of cutting very small parts with erosion-wire diameters of up to $10 \text{ }\mu\text{m}$, high wire

03919537.073101

strengths are demanded in order to reduce deflection and vibration of the wire to a minimum. Tungsten or molybdenum wires have been used up to now for the cutting of very small parts with wire thicknesses of 100 μm and less, however, tungsten or molybdenum wires are extremely expensive to manufacture. Erosion wires with a steel core and a brass outer layer have been unable to be successful up to now for this purpose since they always, in comparison to tungsten wires, showed a lesser strength and a poorer erosion behavior.

SUMMARY OF THE INVENTION

[0004] The basic purpose of the invention is to provide high-strength erosion electrodes with a core of steel of the abovementioned type and a method for their manufacture, which electrodes have strengths which are 1800 N/mm^2 and higher and, in addition, have a comparatively high conductivity of 10 $\text{S}\cdot\text{m/mm}^2$ and more.

BRIEF DESCRIPTION OF THE DRAWING

[0005] The single drawing figure illustrates cross-section of the inventive wire.

DETAILED DESCRIPTION

[0006] This purpose is attained by providing an erosion electrode with a core of steel, an intermediate layer of copper or a high copper-containing alloy and an outer layer with at least 40% zinc, wherein the steel core has a patented structure with a carbon content of 0.6 to 1 wt.%, which occupies an area of the core of 50 to 75% of the cross-sectional surface of the erosion electrode, wherein the intermediate layer has an area of 5 to 40% and the outer layer has an area of 10 to 30%, and wherein the zinc content of the outer layer lies between 40 and 60 wt.%. The purpose is also attained by

providing a method for the manufacture of a high-strength erosion electrode comprising a core of steel, an intermediate layer of copper or a high copper-containing alloy, and an outer layer of an alloy containing at least 40% zinc, wherein a steel with a carbon content of 0.6 to 1 wt.% is used as the core, onto which is applied the intermediate layer of copper or a high copper-containing alloy, wherein an outer layer of zinc or a high zinc-containing alloy is applied onto the intermediate layer, wherein the wire, prior to a first intermediate annealing, is subjected to a diffusion annealing such that on the one hand the outer layer forms an alloy with a zinc content, the melting point of which is higher than the austenitization temperature required for the patenting of the steel core, and on the other hand the diffusion process is carried out so long that, taking into consideration one or rather several following patentings of the erosion wire, the outer layer maintains the desired composition and strength, whereby the erosion electrode is patented during each intermediate annealing.

[0007] Thus, an erosion wire of the invention has a steel core K with a carbon content of 0.6 to 1%, whereby a high copper-containing copper alloy is applied as an intermediate layer ZS onto said steel core. This intermediate layer is covered by an outer layer MS which, when the erosion wire is finished, consists of a zinc alloy, the zinc content of which lies between 40 and 60%. The condition for achieving the comparatively high conductivity of the erosion electrode with an equally high strength is that the core has a patented structure, consists advantageously of sorbite, whereby a further layer is arranged between the outer layer and the core, which further layer contains high amounts of copper, that is, it is only slightly alloyed. Silver in the form of the alloy CuAg1 has here proven to be particularly

advantageous as the alloy element. Also a copper alloy with a small amount of zinc can be advantageously utilized for the intended purpose. An outer layer has been applied to this intermediate layer, which outer layer consists of a zinc alloy, in which the zinc content reaches at least 40% and may reach a maximum of 60%.

[0008] In a second embodiment of the present invention, the erosion electrode is formed from a steel core and an outer layer covering the steel core. The steel core has a patented structure, a carbon content of from 0.6 wt.% and occupies an area of the core of 50 to 75% of the cross-sectional surface of the erosion electrode. The outer layer is a zinc alloy having a zinc content of from 40-60% and forms the balance of the cross-sectional surface of the erosion electrode.

[0009] A wire electrode of the invention could be manufactured in such a manner that a sleeve out of a brass pipe or brass band is applied to a steel core enveloped with copper, and the composite is thereafter reduced by means of wire drawing. This type of manufacture becomes more problematic the higher the zinc content in the outer layer is supposed to be. A further method could consist of providing a copper-enveloped steel wire with a zinc-containing outer layer via a dipping method. The zinc content could here be adjusted at random. The difficulty with this method is to apply the outer layer with an even thickness over the circumference.

[0010] A very advantageous method for the manufacture of a wire electrode is that a steel core is enveloped with a copper layer, whereby the structure of the steel core should exist in a patented form. A zinc alloy is thereafter then applied to this copper intermediate layer, whereby in the simplest case the outer layer consists of pure zinc. This is followed by a diffusion

05919537-073101

annealing, the duration of which is chosen in dependency of the diffusion temperature such that the entire outer layer forms a zinc alloy, the zinc content of which amounts to 60% at a maximum. The duration of the diffusion annealing is furthermore determined such that the demanded areas for the core wire, the intermediate layer and the outer layer adjust, whereby these areas of the three sections are not only important for the strength achieved in the final wire but also for its conductivity. A further decisive factor for the strength, however, and also for the conductivity of the erosion wire is that in the final wire the core consists of a patented structure, whereby the electrical conductivity and strength are equally optimized.

[0011] To prepare the erosion electrode of the present invention according to the second embodiment, an erosion electrode of the first embodiment of the present invention is formed and the electrode subjected to repeated diffusion annealing processes to completely consolidate the intermediate layer into the outer layer.

[0012] The wire, the core of which should already exist in the patented state, is, after the diffusion annealing has occurred, reduced in its diameter by drawing.

[0013] The area of the core on the electrode should lie between 50 to 75% of the entire electrode. The area of the intermediate layer should lie between 5 and 40% and the area of the outer layer between 10 to 30%. If one furthermore meets the demand that the zinc content of the outer layer lies between 40 and 60%, advantageously at slightly above 50%, then one obtains an electrode with a conductivity which lies between 10 and 18 S·m/mm², whereby at the same time strengths are obtained which lie between 1800 and 2500 N/mm². It must hereby be noted that the demand for high conductivity and high strength is in

contrast, namely an inventive wire with a very high strength has a comparatively low electrical conductivity and vice versa. The wires of the invention can be drawn to a diameter of below 10 μm , namely, to diameters which are sufficiently small for the up to now known uses. It has thereby been found to be particularly advantageous that these wires with a thin diameter can easily replace the up to now used tungsten and molybdenum wires and are by comparison significantly less expensive to manufacture, show no aging, have lower raw-material costs, and moreover offer a higher safety in manufacture and have constant erosion characteristics. The achieved quality in manufacture is so great that the wire of the invention will practically not break down on the erosion machine, whereas the breakdown of the up to now utilized molybdenum or tungsten wire amounts to up to 50%.

[0014] The high strength is particularly advantageous in the case of erosion wires with diameters of above 100 μm when workpieces with a greater height are to be cut since high wire tensions are required here in order to keep bending and vibrations low.

[0015] An electrode of the invention is distinguished by a high conductivity and a comparatively high strength. Moreover, the cutting quality with a high exactness in contours is very good, whereby this precision is favored by the high wire tension based on the high strength of the wire.
